Reading the Dataset

HDI Prediction System | Epic 3: Dataset Download and Understanding

Objective

Load the UNDP Human Development Index dataset (HDI.csv) into a pandas DataFrame so it can be explored and later used to train the HDI prediction model.

Dataset Source

The dataset is stored at **Dataset/HDI.csv**. It contains one row per country/territory and one column per indicator-year combination (e.g. "Human Development Index (2021)", "Life Expectancy at Birth (2021)"), covering the years 1990 to 2021.

Code: Loading the Dataset

```
import pandas as pd

# Load the full HDI dataset
df = pd.read_csv("Dataset/HDI.csv")

# Quick look at the first few rows
df.head()
```

What Gets Loaded

Property	Value
Rows (countries/territories)	195
Total columns	880
Identifier columns	ISO3, Country, Human Development Groups, UNDP Developing Regions, HDI Rank (2021)
Indicator columns	Yearly values (1990-2021) for HDI, Life Expectancy, Expected/Mean Years of Schooling, GN

Checking the Load Was Successful

```
print(df.shape)          # (195, 880)
print(df.columns[:8])    # first few column names
print(df['Country'].nunique())  # 195 unique countries
```

Next Step

Once the dataset loads without errors and the shape/column checks look correct, proceed to **Understanding the Dataset** for exploratory analysis before selecting model features.
